

FUNCTIONAL DEPENDENCY THEORY

CS121: Introduction to Relational Database Systems
Fall 2014 – Lecture 19

Last Lecture

2

- Normal forms specify “good schema” patterns
- First normal form (1NF):
 - ▣ All attributes must be atomic
 - ▣ Easy in relational model, harder/less desirable in SQL
- Boyce-Codd normal form (BCNF):
 - ▣ Eliminates redundancy using functional dependencies
 - ▣ Given a relation R and a set of dependencies F
 - ▣ For all functional dependencies $\alpha \rightarrow \beta$ in F^+ , where $\alpha \cup \beta \subseteq R$, at least one of these conditions must hold:
 - $\alpha \rightarrow \beta$ is a trivial dependency
 - α is a superkey for R

Last Lecture (2)

3

- Can convert a schema into BCNF
- If R is a schema not in BCNF:
 - ▣ There is at least one nontrivial functional dependency $\alpha \rightarrow \beta \in F^+$ such that α is not a superkey for R
- Replace R with two schemas:
 - $(\alpha \cup \beta)$
 - $(R - (\beta - \alpha))$
- May need to repeat this decomposition process until all schemas are in BCNF

Functional Dependency Theory

4

- Important to be able to reason about functional dependencies!
- Main question:
 - ▣ What functional dependencies are implied by a set F of functional dependencies?
- Other useful questions:
 - ▣ Which attributes are functionally determined by a particular attribute-set?
 - ▣ What *minimal* set of functional dependencies must actually be enforced in a database?
 - ▣ Is a particular schema decomposition lossless?
 - ▣ Does a decomposition preserve dependencies?

Rules of Inference

5

- Given a set F of functional dependencies
 - ▣ Actual dependencies listed in F may be insufficient for normalizing a schema
 - ▣ Must consider all dependencies logically implied by F
- For a relation schema R
 - ▣ A functional dependency f on R is logically implied by F on R if every relation instance $r(R)$ that satisfies F also satisfies f
- Example:
 - ▣ Relation schema $R(A, B, C, G, H, I)$
 - ▣ Dependencies:
 $A \rightarrow B, A \rightarrow C, CG \rightarrow H, CG \rightarrow I, B \rightarrow H$
 - ▣ Logically implies: $A \rightarrow H, CG \rightarrow HI, AG \rightarrow I$

Rules of Inference (2)

6

- Axioms are rules of inference for dependencies
- This group is called Armstrong's axioms
- Greek letters α , β , γ , ... represent attribute sets
- Reflexivity rule:
If α is a set of attributes and $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$ holds.
- Augmentation rule:
If $\alpha \rightarrow \beta$ holds, and γ is a set of attributes, then $\gamma\alpha \rightarrow \gamma\beta$ holds.
- Transitivity rule:
If $\alpha \rightarrow \beta$ holds, and $\beta \rightarrow \gamma$ holds, then $\alpha \rightarrow \gamma$ holds.

Computing Closure of F

7

Can use Armstrong's axioms to compute F^+ from F

□ F is a set of functional dependencies

$F^+ = F$

repeat

for each functional dependency f in F^+

 apply reflexivity and augmentation rules to f

 add resulting functional dependencies to F^+

for each pair of functional dependencies f_1, f_2 in F^+

if f_1 and f_2 can be combined using transitivity

 add resulting functional dependency to F^+

until F^+ stops changing

Armstrong's Axioms

8

- Axioms are sound
 - ▣ They don't generate any incorrect functional dependencies
- Axioms are complete
 - ▣ Given a set of functional dependencies F , repeated application generates all F^+
- F^+ could be very large
 - ▣ LHS and RHS of a dependency are subsets of R
 - ▣ A set of size n has 2^n subsets
 - ▣ $2^n \times 2^n = 2^{2n}$ possible functional dependencies in R !

More Rules of Inference

9

- Additional rules can be proven from Armstrong's axioms
 - ▣ These make it easier to generate F^+
- Union rule:

If $\alpha \rightarrow \beta$ holds, and $\alpha \rightarrow \gamma$ holds, then $\alpha \rightarrow \beta\gamma$ holds.
- Decomposition rule:

If $\alpha \rightarrow \beta\gamma$ holds, then $\alpha \rightarrow \beta$ holds and $\alpha \rightarrow \gamma$ holds.
- Pseudotransitivity rule:

If $\alpha \rightarrow \beta$ holds, and $\gamma\beta \rightarrow \delta$ holds, then $\alpha\gamma \rightarrow \delta$ holds.

Attribute-Set Closure

10

- How to tell if an attribute-set α is a superkey?
 - ▣ If $\alpha \rightarrow R$ then α is a superkey.
 - ▣ What attributes are functionally determined by an attribute-set α ?
- Given:
 - ▣ Attribute-set α
 - ▣ Set of functional dependencies F
 - ▣ The set of all attributes functionally determined by α under F is called the closure of α under F
 - ▣ Written as α^+

Attribute-Set Closure (2)

11

- It's easy to compute the closure of attribute-set α !
 - ▣ Algorithm is very simple
- Inputs:
 - ▣ attribute-set α
 - ▣ set of functional dependencies F

$\alpha^+ = \alpha$

repeat

for each functional dependency $\beta \rightarrow \gamma$ in F

if $\beta \subseteq \alpha^+$ **then** $\alpha^+ = \alpha^+ \cup \gamma$

until α^+ stops changing

Attribute-Set Closure (3)

12

- Can easily test if α is a superkey
 - ▣ Compute α^+
 - ▣ If $R \subseteq \alpha^+$ then α is a superkey of R
- Can also use with functional dependencies
 - ▣ $\alpha \rightarrow \beta$ holds if $\beta \subseteq \alpha^+$
 - Find closure of α under F ; if it contains β then $\alpha \rightarrow \beta$ holds!
 - ▣ Can compute F^+ with attribute-set closure too:
 - For each $\gamma \subseteq R$, find closure γ^+ under F
 - We know that $\gamma \rightarrow \gamma^+$
 - For each subset $S \subseteq \gamma^+$, add functional dependency $\gamma \rightarrow S$

Attribute-Set Closure Example

13

- Relation schema $R(A, B, C, G, H, I)$
 - Dependencies:
 $A \rightarrow B, A \rightarrow C, CG \rightarrow H, CG \rightarrow I, B \rightarrow H$
- Is AG a superkey of R ?
- Compute $(AG)^+$
 - Start with $\alpha^+ = AG$
 - $A \rightarrow B, A \rightarrow C$ cause $\alpha^+ = ABCG$
 - $CG \rightarrow H, CG \rightarrow I$ cause $\alpha^+ = ABCGHI$
- AG is a superkey of R !

Attribute-Set Closure Example (2)

14

- Relation schema $R(A, B, C, G, H, I)$
 - Dependencies:
 $A \rightarrow B, A \rightarrow C, CG \rightarrow H, CG \rightarrow I, B \rightarrow H$
- Is AG a candidate key of R ?
 - A candidate key is a minimal superkey
 - Compute attribute-set closure of all proper subsets of superkey; if we get R then it's not a candidate key
- Compute the attribute-set closures under F
 - $A^+ = ABCH$
 - $G^+ = G$
- AG is indeed a candidate key!

BCNF Revisited

15

- BCNF algorithm states, if R_i is a schema not in BCNF:
 - ▣ There is at least one nontrivial functional dependency $\alpha \rightarrow \beta$ such that α is not a superkey for R_i
- Two points:
 - ▣ $\alpha \rightarrow \beta \in F^+$, not just in F
 - ▣ For R_i , only care about func. deps. where $\alpha \cup \beta \in R_i$
- How do we tell if R_i is not in BCNF?
 - ▣ Can use attribute-set closure under F to find if there is a dependency in F^+ that affects R_i
 - ▣ For each proper subset $\alpha \subset R_i$, compute α^+ under F
 - ▣ If α^+ doesn't contain R_i , but α^+ does contain any attributes in $R_i - \alpha$, then R_i is not in BCNF

BCNF Revisited (2)

16

- If α^+ doesn't contain R_i , but α^+ does contain any attributes in $R_i - \alpha$, then R_i is not in BCNF
- If α^+ doesn't contain R_i , what do we know about α with respect to R_i ?
 - ▣ α is not a candidate key of R_i
- If α^+ contains attributes in $R_i - \alpha$:
 - ▣ Let $\beta = R_i \cap (\alpha^+ - \alpha)$
 - ▣ We know there is some non-trivial functional dependency $\alpha \rightarrow \beta$ that holds on R_i
- Since $\alpha \rightarrow \beta$ holds on R_i , but α is not a candidate key of R_i , we know that R_i cannot be in BCNF.

BCNF Example

17

- Start with schema $R(A, B, C, D, E)$, and $F = \{ A \rightarrow B, BC \rightarrow D \}$
- Is R in BCNF?
 - ▣ Obviously not.
 - ▣ Using $A \rightarrow B$, decompose into $R_1(\underline{A}, B)$ and $R_2(A, C, D, E)$
- Are we done?
 - ▣ Pseudotransitivity rule says that if $\alpha \rightarrow \beta$ and $\gamma\beta \rightarrow \delta$, then $\alpha\gamma \rightarrow \delta$
 - ▣ $AC \rightarrow D$ also holds on R_2 , so R_2 is not in BCNF!
 - ▣ Or, compute $\{AC\}^+ = ABCD$. Again, R_2 is not in BCNF.

Database Constraints

18

- Enforcing database constraints can easily become very expensive
 - ▣ Especially **CHECK** constraints!
- Best to define database schema such that constraint enforcement is efficient
- Ideally, enforcing a functional dependency involves only one relation
 - ▣ Then, can specify a key constraint instead of a multi-table **CHECK** constraint!

Example: Personal Bankers

19

- Bank sets a requirement on employees:
 - ▣ Each employee can work at only one branch
 - ▣ *emp_id* → *branch_name*
- Bank wants to give customers a personal banker at each branch
 - ▣ At each branch, a customer has only one personal banker
 - ▣ (A customer could have personal bankers at multiple branches.)
 - ▣ *cust_id, branch_name* → *emp_id*

Personal Bankers

20

□ E-R diagram:

□ Relationship-set schemas:

works_in(emp_id, branch_name)

cust_banker_branch(cust_id, branch_name, emp_id, type)

Personal Bankers (2)

21

□ Schemas:

works_in(*emp_id*, *branch_name*)

cust_banker_branch(*cust_id*, *branch_name*, *emp_id*, *type*)

□ Is this schema in BCNF?

□ *emp_id* → *branch_name*

□ *cust_banker_branch* isn't in BCNF

■ *emp_id* isn't a candidate key on *cust_banker_branch*

□ *cust_banker_branch* repeats *branch_name* unnecessarily,
since *emp_id* → *branch_name*

□ Decompose into two BCNF schemas:

□ *works_in* already has (*emp_id*, *branch_name*) ($\alpha \cup \beta$)

□ Create *cust_banker*(*cust_id*, *emp_id*, *type*) ($R - (\beta - \alpha)$)

Personal Bankers (3)

22

- New BCNF schemas:

works_in(*emp_id*, *branch_name*)

cust_banker(*cust_id*, *emp_id*, *type*)

- ▣ A customer can have one personal banker at each branch, so both *cust_id* and *emp_id* must be in the primary key

- Any problems with this new BCNF version?

- ▣ Now we can't easily constrain that each customer has only one personal banker at each branch!
- ▣ Could still create a complicated **CHECK** constraint involving multiple tables...

Preserving Dependencies

23

- The BCNF decomposition doesn't preserve this dependency:
 - ▣ $cust_id, branch_name \rightarrow emp_id$
 - ▣ Can't enforce this dependency within a single table
- In general, BCNF decompositions are not dependency-preserving
 - ▣ Some functional dependencies are not enforceable within a single table
 - ▣ Can't enforce them with a simple key constraint, so they are more expensive
- Solution: Third Normal Form

Third Normal Form

24

- Slightly weaker than Boyce-Codd normal form
 - ▣ Preserves more functional dependencies
 - ▣ Also allows more repeated information!
- Given:
 - ▣ Relation schema R
 - ▣ Set of functional dependencies F
- R is in 3NF with respect to F if:
 - ▣ For all functional dependencies $\alpha \rightarrow \beta$ in F^+ , where $\alpha \subseteq R$ and $\beta \subseteq R$, at least one of the following holds:
 - $\alpha \rightarrow \beta$ is a trivial dependency
 - α is a superkey for R
 - Each attribute A in $\beta - \alpha$ is contained in a candidate key for R

Third Normal Form (2)

25

- New condition:
 - ▣ Each attribute A in $\beta - \alpha$ is contained in a candidate key for R
- A general constraint:
 - ▣ Doesn't require a single candidate key to contain all attributes in $\beta - \alpha$
 - ▣ Just requires that each attribute in $\beta - \alpha$ appears in *some* candidate key in R
 - ▣ ...possibly even different candidate keys!

Personal Banker Example

26

- Our non-BCNF personal banker schemas again:
 - *works_in*(*emp_id*, *branch_name*)
 - *cust_banker_branch*(*cust_id*, *branch_name*, *emp_id*, *type*)
- Is this schema in 3NF?
 - $emp_id \rightarrow branch_name$
 - $cust_id, branch_name \rightarrow emp_id$
- *works_in* is in 3NF (*emp_id* is the primary key)
- What about *cust_banker_branch* ?
 - Both dependencies hold on *cust_banker_branch*
 - $emp_id \rightarrow branch_name$, but *emp_id* isn't the primary key
 - $cust_id, branch_name \rightarrow emp_id$; is *emp_id* part of any candidate key on *cust_banker_branch* ?

Personal Banker Example (2)

27

- Look carefully at the functional dependencies:
 - ▣ Primary key of *cust_banker_branch* is (*cust_id*, *branch_name*)
 - $\{ \text{cust_id}, \text{branch_name} \} \rightarrow \text{cust_banker_branch}$ (all attributes)
(constraint arises from the E-R diagram & schema translation)
 - (Also specified this constraint: $\text{cust_id}, \text{branch_name} \rightarrow \text{emp_id}$)
 - ▣ We also know that $\text{emp_id} \rightarrow \text{branch_name}$
 - ▣ Pseudotransitivity rule: if $\alpha \rightarrow \beta$ and $\gamma\beta \rightarrow \delta$, then $\alpha\gamma \rightarrow \delta$
 - $\{ \text{emp_id} \} \rightarrow \{ \text{branch_name} \}$
 - $\{ \text{cust_id}, \text{branch_name} \} \rightarrow \text{cust_banker_branch}$
 - Therefore, $\{ \text{emp_id}, \text{cust_id} \} \rightarrow \text{cust_banker_branch}$ also holds!
 - ▣ (*cust_id*, *emp_id*) is a candidate key of *cust_banker_branch*
- So *cust_banker_branch* is in fact in 3NF
 - ▣ (And we need to enforce this second candidate key too...)

Canonical Cover

28

- Given a relation schema, and a set of functional dependencies F
- Database needs to enforce F on all relations
 - ▣ Invalid changes should be rolled back
- F could contain a lot of functional dependencies
 - ▣ Dependencies might even logically imply each other
- Want a minimal version of F , that still represents all constraints imposed by F
 - ▣ Should be more efficient to enforce minimal version

Canonical Cover (2)

29

- A canonical cover F_c for F is a set of functional dependencies such that:
 - ▣ F logically implies all dependencies in F_c
 - ▣ F_c logically implies all dependencies in F
 - ▣ Can't infer any functional dependency in F_c from other dependencies in F_c
 - ▣ No functional dependency in F_c contains an extraneous attribute
 - ▣ Left side of all functional dependencies in F_c are unique
 - There are no two dependencies $\alpha_1 \rightarrow \beta_1$ and $\alpha_2 \rightarrow \beta_2$ in F_c such that $\alpha_1 = \alpha_2$

Extraneous Attributes

30

- Given a set F of functional dependencies
 - ▣ An attribute in a functional dependency is extraneous if it can be removed from F without affecting closure of F
- Formally: given F , and $\alpha \rightarrow \beta$
 - ▣ If $A \in \alpha$, and F logically implies $(F - \{\alpha \rightarrow \beta\}) \cup \{(\alpha - A) \rightarrow \beta\}$, then A is extraneous
 - ▣ If $A \in \beta$, and $(F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\}$ logically implies F , then A is extraneous
 - i.e. generate a new set of functional dependencies F' by replacing $\alpha \rightarrow \beta$ with $\alpha \rightarrow (\beta - A)$
 - See if F' logically implies F

Testing Extraneous Attributes

31

- Given relation schema R , and a set F of functional dependencies that hold on R
- Attribute A in $\alpha \rightarrow \beta$
- If $A \in \alpha$ (i.e. A is on left side of the dependency), then let $\gamma = \alpha - \{A\}$
 - ▣ See if $\gamma \rightarrow \beta$ can be inferred from F
 - ▣ Compute γ^+ under F
 - ▣ If $\beta \subseteq \gamma^+$, then A is extraneous in α

Testing Extraneous Attributes (2)

32

- Given relation schema R , and a set F of functional dependencies that hold on R
- Attribute A in $\alpha \rightarrow \beta$
- If $A \in \beta$ (on right side of the dependency), then try the altered set F'
 - ▣ $F' = (F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\}$
 - ▣ See if $\alpha \rightarrow A$ can be inferred from F'
 - ▣ Compute α^+ under F'
 - ▣ If α^+ includes A , then A is extraneous in β

Computing Canonical Cover

33

- A simple way to compute the canonical cover of F

$$F_c = F$$

repeat

 apply union rule to replace dependencies in F_c of form

$$\alpha_1 \rightarrow \beta_1 \text{ and } \alpha_1 \rightarrow \beta_2 \text{ with } \alpha_1 \rightarrow \beta_1\beta_2$$

 find a functional dependency $\alpha \rightarrow \beta$ in F_c with an
 extraneous attribute

 /* Use F_c for the extraneous attribute test, not F !!! */

 if an extraneous attribute is found, delete it from $\alpha \rightarrow \beta$

until F_c stops changing

Canonical Cover Example

34

- Functional dependencies F on schema (A, B, C)
 - ▣ $F = \{ A \rightarrow BC, B \rightarrow C, A \rightarrow B, AB \rightarrow C \}$
 - ▣ Find F_c
- Apply union rule to $A \rightarrow BC$ and $A \rightarrow B$
 - ▣ Left with: $\{ A \rightarrow BC, B \rightarrow C, AB \rightarrow C \}$
- A is extraneous in $AB \rightarrow C$
 - ▣ $B \rightarrow C$ is logically implied by F (obvious)
 - ▣ Left with: $\{ A \rightarrow BC, B \rightarrow C \}$
- C is extraneous in $A \rightarrow BC$
 - ▣ Logically implied by $A \rightarrow B, B \rightarrow C$
- $F_c = \{ A \rightarrow B, B \rightarrow C \}$

Another Canonical Cover Example

35

- Functional dependencies F on schema (A, B, C, D)
 - ▣ $F = \{ A \rightarrow B, BC \rightarrow D, AC \rightarrow D \}$
 - ▣ Find F_c
- Satisfies some of our constraints for $F_c...$
 - ▣ No functional dependency has extraneous attributes
 - ▣ All dependencies have a unique lefthand side
- Problem:
 - ▣ Can infer $AC \rightarrow D$ from the other two dependencies (pseudotransitivity)
 - ▣ Could argue that D is extraneous in $AC \rightarrow D$ (a bit weird)
 - ▣ Or, just argue that the entire dependency is extraneous

Canonical Covers

36

- A set of functional dependencies can have multiple canonical covers!
- Example:
 - ▣ $F = \{ A \rightarrow BC, B \rightarrow AC, C \rightarrow AB \}$
 - ▣ Has several canonical covers:
 - $F_c = \{ A \rightarrow B, B \rightarrow C, C \rightarrow A \}$
 - $F_c = \{ A \rightarrow B, B \rightarrow AC, C \rightarrow B \}$
 - $F_c = \{ A \rightarrow C, C \rightarrow B, B \rightarrow A \}$
 - $F_c = \{ A \rightarrow C, B \rightarrow C, C \rightarrow AB \}$
 - $F_c = \{ A \rightarrow BC, B \rightarrow A, C \rightarrow A \}$
